Observations at Swedish Lightships and in  
the Central Baltic.

Hydrography of the Kattegatt and the Skagerrak  
Area, Swedish Observations, 1969.

(Contribution to ICES "Annales Biologiques" 1970)

by  
Stig H. Fonselius and Artur Svansson

June 1970

Observations at Swedish Lightships and in the Central Baltic in 1969.

During the year the lightship "Finngrundet" has been replaced by an unmanned lighthouse built on a caisson. Hydrographic observations have instead been taken up at the lightship "Västra Banken" at the western border of the Finngrundsbankarna. The position of the "Västra Banken" is  $60^{\circ} 54' N$  and  $17^{\circ} 56' E$ . The measurements began in July and are carried out to a depth of 25 m. Table 1 shows monthly means of salinity and temperature in 1969 at surface and bottom at Swedish lightships with deviations from the 30-year means. The monthly means at "Västra Banken" have been compared to the 30-year means at "Finngrundet" and the deviations from these means are given in the table. The 25 m values have been compared to the corresponding 30 m long time value at "Finngrundet". The deviation are small, but longer series may be needed in order to be able to conclude if the "Västra Banken" values can be considered as a continuation of the values from "Finngrundet". No general conclusions concerning the conditions in the Baltic, can be drawn from the lightship observations.

Table 2 shows the hydrographic parameters in the Arkona basin, the Bornholm basin, the Gotland basin and the Landsort Deep during 1969. It was mentioned in the report for 1968 (Fonselius 1969a) that new high saline water began to stream in to the Baltic at the end of 1968. This inflow is demonstrated in fig. 1 which shows the changes in density in the Arkona basin from September 1968 to November 1969. It can be seen that there has occurred two different inflows of high saline water, the first in October-December 1968 and the second in February-April 1969. Fig. 2 shows the density changes in the Bornholm basin during the same period. It can be seen that the first inflow did not penetrate to the bottom of the Bornholm basin. The second inflow, however, renewed the bottom water, forcing out the  $H_2S$ . Table 2b shows that there was 2.39 ml oxygen per liter in the deep water in January 1969. In April the oxygen value had increased to 6.30 ml/l at 87 m depth. Fig. 3 shows the salinity changes in the Gotland Deep from September 1968 to January 1970. During the autumn the high saline water obviously has penetrated to the bottom of the Gotland Deep. From table 2c it can be seen that the  $H_2S$  in November has been driven out from the bottom of the basin and that the new water at 240 m contains 1.81 ml oxygen/l. Lower values are found in the water above that level. Fig. 4 shows the development of the oxygen and hydrogen sulfide conditions in the Gotland basin from 1966 to January 1970. A total renewal of the deep water has occurred during 1969. The old stagnant water has been driven out from the basin and has been forced

northwards to the northern Central basin. High  $H_2S$  values are now found in the Landsort Deep. From table 2d it can be seen that the  $H_2S$  values increase continuously in the Landsort Deep and that the  $H_2S$  contaminated water in November extends up to above 150 m.

It may be concluded that the deep water of the Baltic proper, probably will be totally renewed during 1970. All the accumulated nutrients will eventually be brought to the surface water "fertilizing" it. This will increase the primary production enormously and will cause an increased oxygen utilization in the deep water (Fonselius 1969b). The final result will be a new  $H_2S$  formation in the deep water of the Baltic proper.

It has to be pointed out that the total P values in the deep water of the Landsort Deep in January and April are considerably lower than corresponding the phosphate-phosphorus values (table 2d). The reason for this error has not been found. It is not possible at present to judge if the  $PO_4^3-$ -P or the Total-P values are erroneous. Therefore the author has preferred to publish both values.

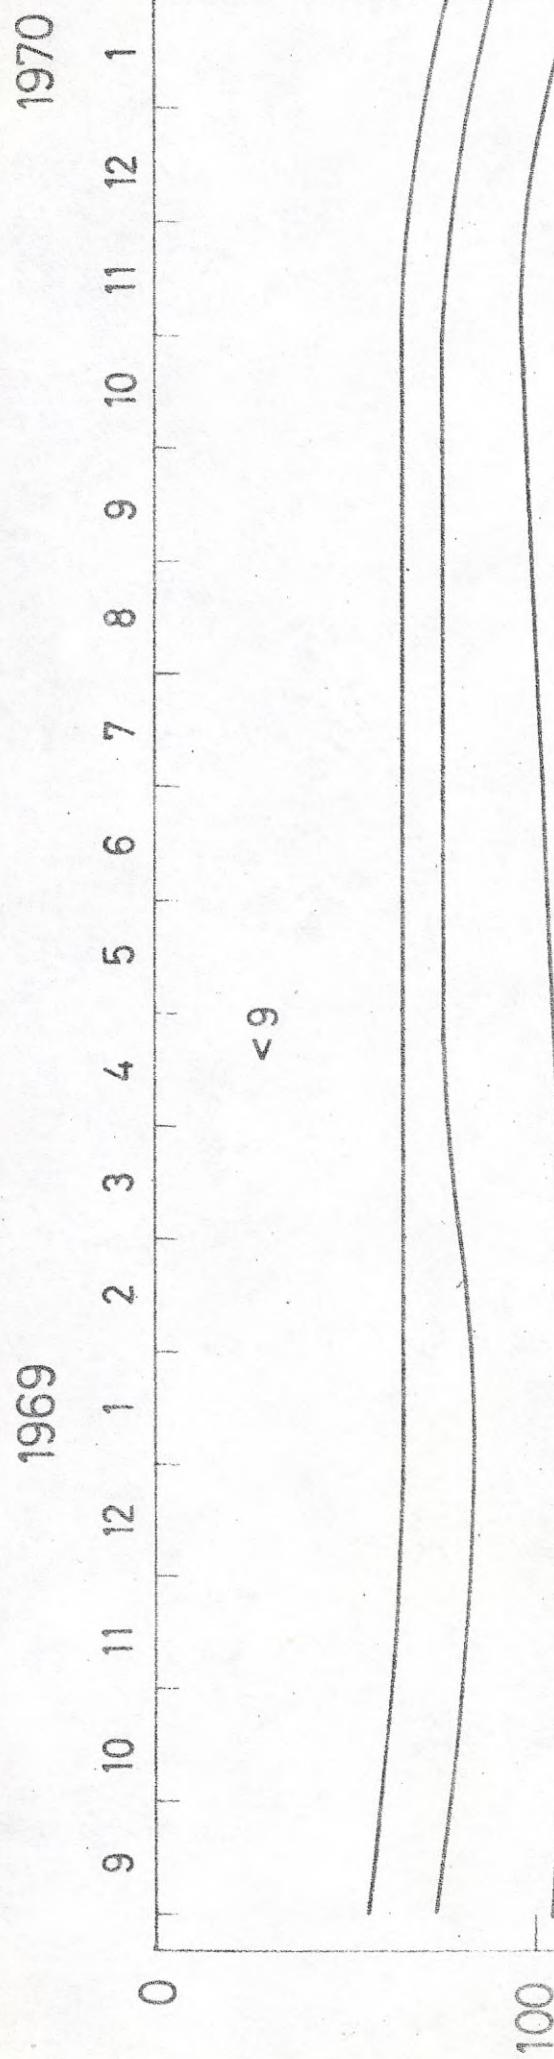

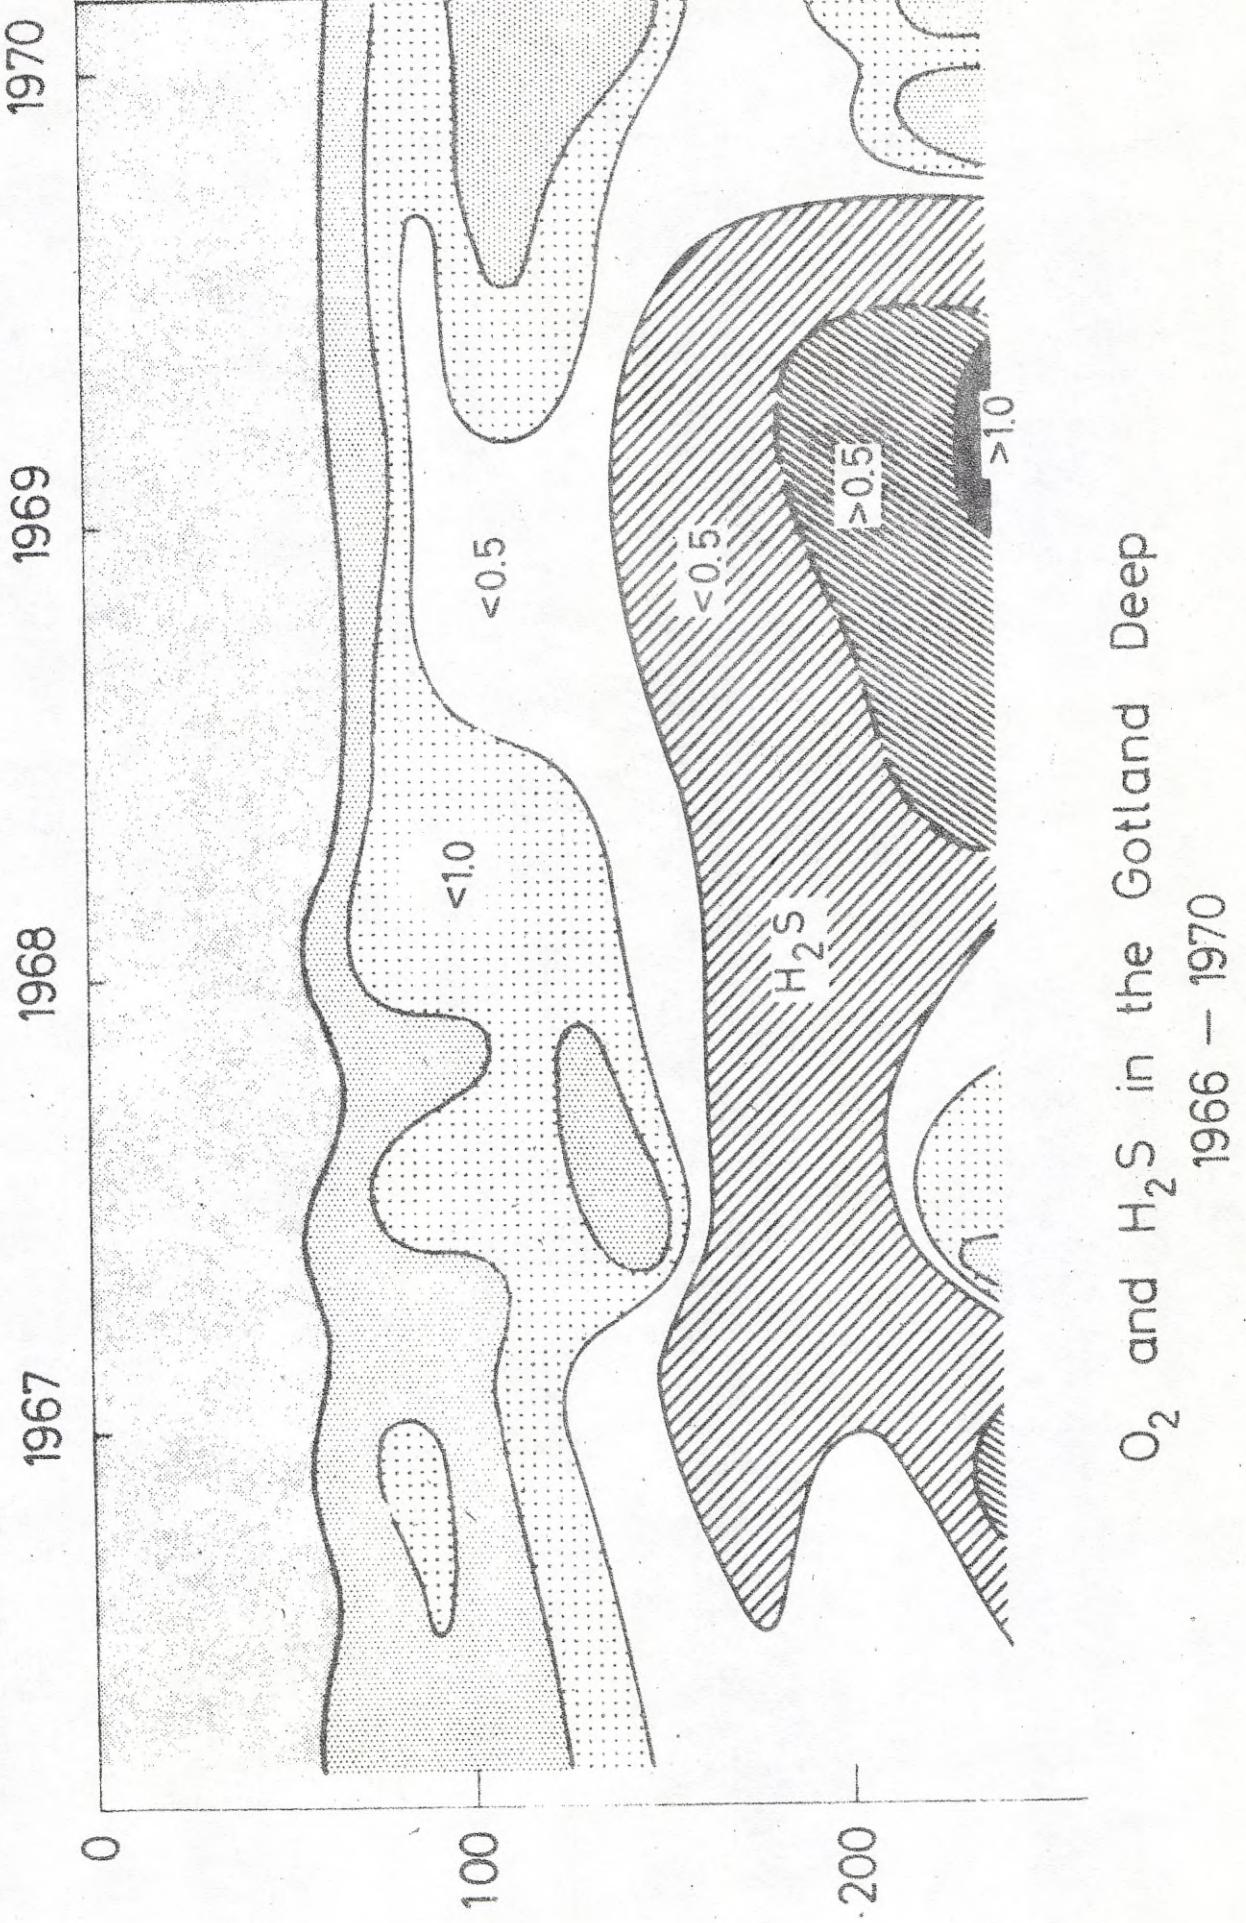

Fig. 4

Hydrography of the Kattegat and the Skagerrak Area,  
Swedish Observations 1969.

Table 1 presents monthly mean values of temperature and salinity at the lightship Fladen until the vessel left its position for ever. The anomalies of bottom salinity were positive throughout the whole period January-September. The negative correlation between surface and bottom temperatures is striking.

Tables 2 and 3 contain oxygen values from the Kattegat area (Station D from Town of Göteborg investigations). The fact that the minimum values this year are higher than the year before may be due to the many violent storms in September and October.

The sections P and Å (See map) were visited in March, June, August and December (Section P also in October). Oxygen were determined everywhere when temperature and salinity were measured. Fig. 1 presents the conditions in March. The lowest value at the deeper parts of the P section at this occasion was 81 %, while in June it was 85 %, in August 81 %, October 91 % and in December 90 %.

The present Fig. 2 was already published in Annales Biologiques of the year 1967 but is reproduced here brought up to date. The winter period in the beginning of the year was apparently cold enough to lower the temperature down to 600 m.
